Generalitation à uniform convergence
Def A tentered RV X is 6-8WGanssian laro-SG; variance may 6^2) If $\mathbb{E} \exp(\chi x) \leq \exp(\chi^2 \delta^2/2)$, $\forall \lambda \in \mathbb{R}$.
Lemma If X is 6-subGaussian, that for any $\xi > 0$, $P(X \ge \xi) \le \exp(-\xi/26^2)$. Pf: Exercise. Hint: Note that $P(X \ge \xi) = \inf_{t \ge 0} P(\exp(tX)) \ge \exp(t\xi)$.
-Bounded RV'S are SG. Exercise: If Xela, SJas, X is SG. I ramand proxy (6-9)3/4 Gaussians are SG Sums of SG are SG.
Homework O: A X, X, we indep. 6SG RV's than

Homework 0: if X_1 , X_1 are indep. $6_{\overline{i}}$ -SG RN's, then $Z:=\sum_{i=1}^{n}X_i$ is SG with variance proxy $\sum_{i=1}^{n}6_{i}^{2}$; and if X_{70} then X_{7} : is X_{6} : X_{6} -SG (variance proxy: $X_{7}^{2}6_{i}^{2}$). Thus, if

-s as ugets larger, sample mean closer to pop mean. EX. Let (X,4) of P, Xerrd, YESTIS, f: Rd -> St 15, and let \$ Zi := 1 (f(xi) \$ yi). Then end Zi is iid, bounded, (hence SG: with variance proxy 4). So by above, w.p. > 1-8, $P(y \neq f(x)) \leq \frac{1}{N} \leq \frac{1}{N} \left(\frac{1}{N} \left(\frac{y}{y} + \frac{1}{N} \frac{y}{y} \right) \right) + \sqrt{\frac{10y(2/8)}{2n}}$ - test error is bounded by train error +0(5). Example. Suppose (x:, 4i), are iid. For any ne1N, define: $f_{n}(x) := \begin{cases} y_i: x \in \{x_1, ..., x_n\}, \\ -10: \text{ otherwise} \end{cases}$ Consider two situations: (1) X has finite support. Then $t_1 \leq_1^n \int_{-\infty}^{\infty} \int$ and TP(y f f(x1) -> 0 as vell, since we trecover all pts. (2) X has continues distriction $\pm 2^n (1/y \neq f(x_i)) = 0$ by construction,

but $\mathbb{P}(y \neq f(x)) = 1 \text{ fn.}$

What broke sur a contentration? Firs a random variable. Although (ki, yi) are ild, Z:= 1(yiff(xi)) me hot independent. (2) is overfitting: [(f)=0 but L(f)=1. How can we gravantee test error is small what looking at training error? We'll see how via uniform convergence: For iid Zin loss ((Zi), $L(f) := \mathbb{E} f(2), \quad 2(f) = \frac{1}{h} 2 \frac{1}{h} f(2i),$ Goal: bound L(f). Suppose $f \in J$, some for class J.

And suppose we use S = 52i2i to fi+f=f(S). Then we typically lose indep of f(2i)S. Approach is thou: L(f) = L(f) - L(f) + L(f)< L(f) + Syf & L(f) - Z(f) \. Seems very silly, but we will see very fruitful to loss. We'll prove deviation bonds that had uniformly over fef.

Example. Let $f = \{f_1, f_k\}, |f_k\}, |f_k| \text{ If } (x_i, y_i)^*$ are itd, $f_i: \mathbb{R}^d > \{t^i\}, \text{ then } SG \text{ concentration as before gives for fixed } f_i,$ $\mathbb{M}\left(\left| P(f(x) \neq y) - \frac{1}{h} \sum_{i=1}^{h} d(y_i \neq f(x_i)) \right| > \sqrt{\frac{10^{28}}{2n}} \right) \leq \epsilon$ surfacely, wy >1-5, $|P(f_{\ell}A\neq y)-P(f_{\ell}A\neq y)|\leq \int \frac{1693}{N}$. 1 Mion bound: $\mathbb{P}\left(\exists \text{leth} : |\mathbb{P}(f_{\ell}(x) \neq y) - \widehat{\mathbb{P}}(f_{\ell}(x) \neq y)| = \sqrt{\frac{\log^2 k}{2}}\right) \leq k \cdot \frac{\delta}{k} = k.$ i.e. up > 1-8, for all (c[le], $|P(y+f)|A) - \hat{P}(f)(A \neq y)| \leq \int_{-2.15}^{169(24/8)}$ $\leq \left(\frac{\log |\mathcal{F}|}{2h} + \frac{\log (48)}{2h}\right)$ For finite classes, get Just extra term. We'll see next that Rademadrer complexity allows for dealing of 191-00.

Def. For VCRh, the unormalized/normalized Redeliacher complexity is WRad(V):= # 84 < \\ , u > , Rad(V) = to URad(V), where ECR" is iid Rademacher: 2: ~ Wrif (9 + 12). We will typically apply this to outputs of a function class over training data. E.g. for $2i = (x_i, y_i)$, $S = \{2i, 2i\}$, for class = 1, 715 == S(f(z1), ..., f(zn)): fefé. -> URad(F/s) = F sw (E,u) = F sup 5, E; f(Zi). - Whad (fis) is large if, for any E; Eqt 1's, there is some fef st f(zi)=zi. - If we think of f(z;) e {+1}, then this corresponds to I fitting "random labels" - We'll aften work at WRad for wsses, i.e. for I, URad ((l.f)15) = URad ((l(y,f(x,1),.., l(ynf(xn))): fef).

- Rad (V) vaughly measures how large/complicated V is.

Properties: (i) URad (Suz) = E < E, u) =0. 2) WRad(V+qu2)=WRad (qv+u: veV?) = WRad(V). 3) If VCV', URad (V) = URad (V'). (3+12") = F 50 × (5+12" € 1×12" = M. -> Still is as large as possible among vectors taking rule in ±1. (S) Mad (3(-1,-1,-1), (1,,1) ?) = E max { Zzi, -Zzi? - E | Zzi |. $|Z_{i}^{n}Z_{i}| = |Z_{i}^{n}(2.Ber(\frac{1}{2}) - 1)| = |2.Bin(n,\frac{1}{2}) - M|.$ Anti-concentration of Binomial Shows |2Bin(n, 1) - n| = (4)(5n). You will also sometimes see an absolute value version of Rad, compense,

Wrad (V):= FEz Sulver / 12,57/.

Similar idea, but a sit less nice for reasons we won't get into.

A(2) € [9, b] \ 2, \ \ f €], let IP: distriver Theorem. Let I be a for class u (1) For cany & (0,1), w.p. >1-8, Sup SE(a), w.p. Z, S(a) $Z = E(sup) = E(a) - E(f(a)) + (b-a) \int \frac{160}{a} da$. (2) wp > 1-8, $Rad(f_{|s}) \leq Rad(f_{|s}) + (5-a) \int \frac{195148}{2h}$ (3) up > 1-8, $\sup_{f \in \mathcal{F}} \{ \text{LF}(z) - \frac{1}{h} \text{E}_{i}^{n}f(z) \} \leq 2 \text{Rad}(\mathcal{F}_{|s}) + 3(b-a) \int_{n}^{\log \frac{\pi}{2}} \frac{\log \frac{\pi}{2}}{n}$ To prove this, we'll use MaDiarmid's ineq: This (MacDiannia). Supple F: Rh-IR satisfies bounded differences: ∀i∈[h], if ci st Sup [F(z₁,..., z₁, z₁,..., z_n)-F(z₁,..., z_n)| ≤ (i. Than, z₁,..., z_n) | ≤ (i. Than, z_n, z_n, z_n, z_n) | ≤ (i.
